# Conceptual Exercises

Training/test error for subset selection

# 1. Generating data

```
# Set seed
set.seed(110)
# Generate variables
x_raw = runif(20000, -1, 1)
x = matrix(x_raw, nrow=1000, ncol=20)
beta = runif(20, 0, 10)
beta[18:20] = 0
# Error term
ep = rnorm(1000, 0, 0.25)
# Response vector
y = x %*% beta + ep
# Put them into one dataframe
df = data.frame(x, y)
```

### 2. Split data

```
train = df[0:900,]
test = df[901:1000,]
```

#### 3. Subset selection

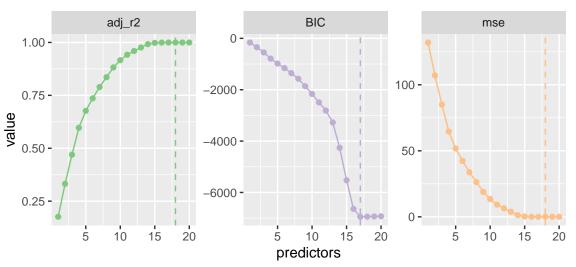

```

```

MSE is calculated by residual sum of squared divided by degrees of freedom.

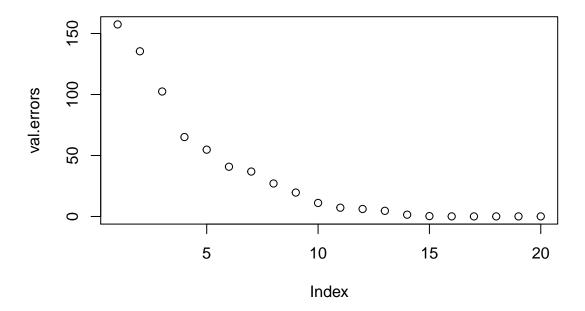

```
# best models per each information loss metric
results_best <- tibble(
  mse = which.min(results$rss / (900 - apply(results$which, 1, sum))),
  `adj_r2` = which.max(results$adjr2), # Adjusted r-squared

plot(val.errors)
```

### **5.**

From the MSE results above, the best model which has the minimum MSE is the model 17th, which contains all except three independent variables whose coefficients I assigned zero. This means that the subset selection properly identifies the true model.

# 6.

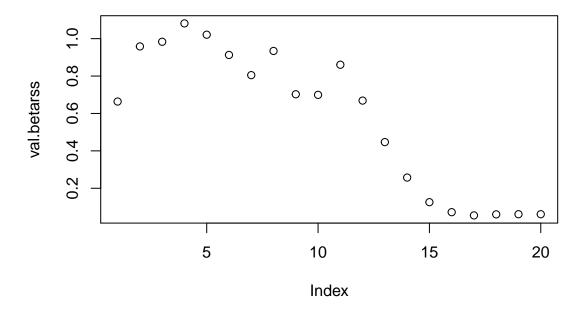

The estimated coefficients and the true intercept are the following:

	Beta_hat	sd	True_Beta
Intercept	-0.0018463	0.0085255	-0.0031689
X1	2.8757756	0.0147096	2.8598673
X2	5.2040917	0.0145610	5.2264123
X3	8.5817494	0.0147709	8.5620547
X4	9.6956283	0.0144018	9.6951894
X5	0.8273899	0.0150899	0.8315567
X6	5.1321769	0.0146162	5.1495462
X7	6.5319993	0.0145969	6.5341731
X8	0.2779805	0.0145105	0.2760716
X9	4.9916629	0.0146399	4.9921238
X10	3.2276018	0.0145564	3.2268088

•	Beta_hat	$\operatorname{sd}$	True_Beta
X11	1.6728623	0.0147579	1.7016324
X12	3.7577918	0.0151946	3.7506407
X13	3.0491317	0.0149944	3.0517023
X14	8.6276771	0.0144434	8.6233271
X15	8.0467667	0.0147525	8.0309498
X16	2.6441161	0.0148271	2.6250869
X17	4.7617181	0.0142295	4.7565895
X18	NA	NA	0.0000000
X19	NA	NA	0.0000000
X20	NA	NA	0.0000000

As shown above table, the estimated coefficients are close to the true beta. Under parametric test, the distance between the two is closer than twice the standard deviation, meaning that the difference is not statistically significant with 5% level.

## 7.

The 17th model gets the minimum value, which is the same as we got with training set.

# Application exercises

## The General Social Survey

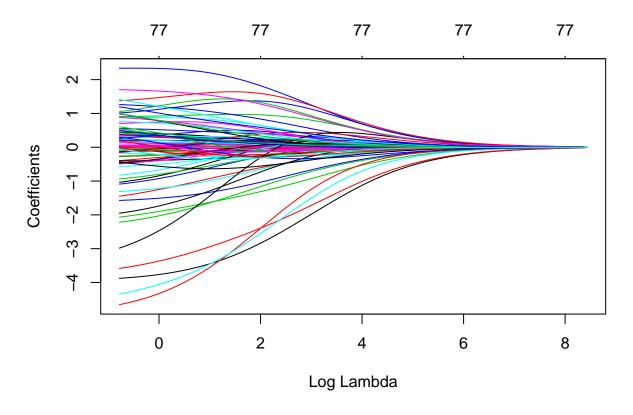

## 1. Least Squares Linear Model

```
gss_train <- read.csv('data/gss_train.csv')
gss_test <- read.csv('data/gss_test.csv')

ls_model <- lm(egalit_scale ~ ., data=gss_train)
ls_pred <- predict(ls_model, gss_test)
ls_mse <- mean((ls_pred - gss_test$egalit_scale)^2)
ls_mse</pre>
```

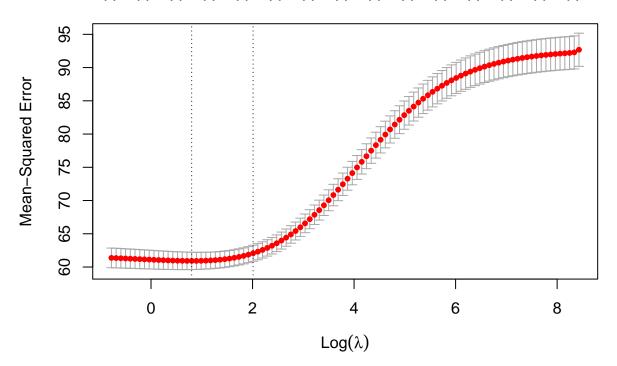

## [1] 63.21363

#### 2. Ridge Regression Model

```
ridge_cv <- cv.glmnet(
    x = gss_train_x,
    y = gss_train_y,
    alpha = 0,
    nfolds = 10
)
plot(ridge_cv)</pre>
```

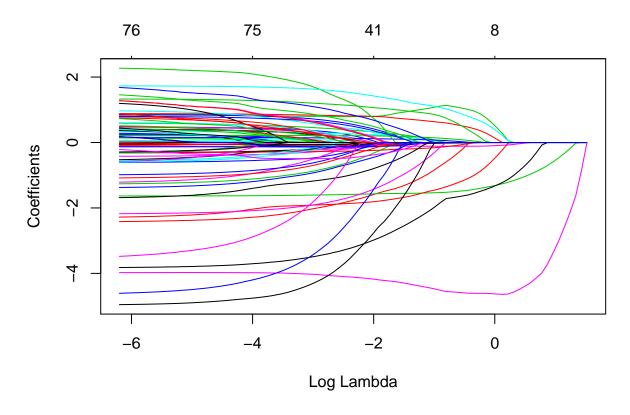

# 

```
ridge_best <- ridge_cv$lambda.min
ridge_pred <- predict(ridge_model, s = ridge_best, newx = gss_test_x)
ridge_mse <- mean((ridge_pred - gss_test_y)^2)
ridge_mse</pre>
```

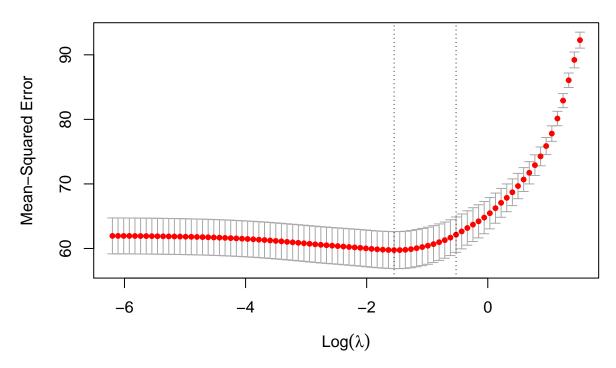

## [1] 61.03781

## 3. Lasso Regression

```
lasso_cv <- cv.glmnet(
  x = gss_train_x,
  y = gss_train_y,
  alpha = 1,
  nfolds = 10
)
plot(lasso_cv)</pre>
```

# 76 76 76 73 74 62 59 50 33 22 14 8 4 3 2 1

```
lasso_best <- lasso_cv$lambda.min
lasso_pred <- predict(lasso_model, s = lasso_best, newx = gss_test_x)
lasso_mse <- mean((lasso_pred - gss_test_y)^2)
lasso_mse</pre>
```

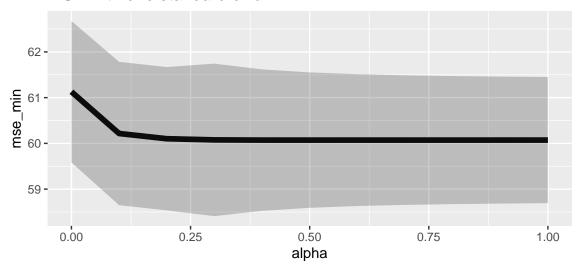

## [1] 61.22341

#### 4. Elastic Net Regression Model

```
# maintain the same folds across all models
fold_id <- sample(1:10, size = length(gss_train_y), replace = TRUE)</pre>
# search across a range of alphas
tuning_grid <- tibble::tibble(</pre>
  alpha
             = seq(0, 1, by = .1),
  mse_min
             = NA
             = NA
  mse_1se
  lambda_min = NA,
  lambda_1se = NA,
  non_zero = NA,
  test_mse = NA
for(i in seq_along(tuning_grid$alpha)) {
  \#\ fit\ CV\ model\ for\ each\ alpha\ value
  fit <- cv.glmnet(gss_train_x,</pre>
                    gss_train_y,
```

```
alpha = tuning_grid$alpha[i],
                    foldid = fold_id)
  # extract MSE and lambda values
  tuning_grid$mse_min[i]
                            <- fit$cvm[fit$lambda == fit$lambda.min]
  tuning_grid$mse_1se[i]
                            <- fit$cvm[fit$lambda == fit$lambda.1se]
  tuning_grid$lambda_min[i] <- fit$lambda.min</pre>
  tuning_grid$lambda_1se[i] <- fit$lambda.1se</pre>
  tuning_grid$non_zero[i] <- fit$nzero[fit$lambda == fit$lambda.min]</pre>
  ela_best <- fit$lambda.min</pre>
  ela_pred <- predict(fit, s = ela_best, newx = gss_test_x)</pre>
  ela_mse <- mean((ela_pred - gss_test_y)^2)</pre>
 tuning_grid$test_mse[i] <- ela_mse</pre>
tuning_grid %>%
  mutate(se = mse_1se - mse_min) %>%
  ggplot(aes(alpha, mse_min)) +
  geom_line(size = 2) +
  geom_ribbon(aes(ymax = mse_min + se, ymin = mse_min - se), alpha = .25) +
  ggtitle("MSE with one standard error")
```

# MSE with one standard error

```
tuning_grid %>%
filter(mse_min == min(mse_min))
```

alpha	mse_min	mse_1se	lambda_min	lambda_1se	non_zero	test_mse
0.7	60.07186	61.48857	0.3039779	0.7022284	29	61.18543

```
ela_mse <- tuning_grid %>%
  filter(mse_min == min(mse_min)) %>%
  select(test_mse) %>%
  pull
```

From the results above, the lowest cross-validation MSE is under the combination of  $\alpha = 0.7$  where non-zero coefficients are 29. The test MSE on that model is 61.18, which is in the middle of the results of Ridge and Lasso.

#### 5. Comments

To capture the accuracy, I calculate R squared for each model:

$$R^{2} = 1 - \frac{MSE}{\frac{1}{n} \sum_{i=1}^{n} (y_{i} - \bar{y})^{2}}$$

model	MSE	R2
LS Linear	63.21363	0.3004585
Ridge	61.03781	0.3245369
Lasso	61.22341	0.3224829
$Elastic\_Net$	61.18543	0.3229033

From the results above, the best model is Ridge regression model. However, the MSEs and R squares are close to each other, so model does not matter very much. The R squared indicates that the model explains the dependent variable (egalitarianism) about 30%, which is low for prediction.
